

# Optimization Algorithm Tailored for Embedded Model Predictive Control

author<sup>1</sup>

*Abstract*—Write an abstract here.

## I. INTRODUCTION

Write the introduction here.

## II. RELATED WORK

### A. Model predictive control

List some literature with information about model predictive control (MPC).

### B. Solving optimization problems

Many Algorithms which use primal dual methods to solve several optimization problems and give solutions with high accuracy are described in literature. For application as MPC, optimization often do not necessarily has to find such exact solutions, therefore in [1] a primal barrier method with focus of getting fast sufficiently exact solutions of quadratic programs is described, where the special MPC problem structure is made use of. This paper's contribution is mainly based on the algorithm in [1], which has been extended by some numerical robustness approaches and for application to more general optimization problems, especially QCQPs and SOCPs.

## III. PROBLEM STATEMENT

### A. Description of a Quadratic Program

Introduce the unchanged problem statement of [1]

### B. Quadratic Constrained Quadratic Program

If linear constraints as bounds for state and control variable are not sufficient it can be necessary to use nonlinear constraints such as quadratic constraints

$$z^T \Gamma z + \beta^T z \leq \alpha. \quad (1)$$

### C. Second Order Cone Program

A more general form of constraints are second order cone constraints. The constraints of such second order cone program can be formulated as following inequality:

$$\|Az + b\|_2 \leq c^T z + d. \quad (2)$$

### D. Soft Constraints

## IV. EXTENDED ALGORITHM

### A. Generalized Constraints

In the described primal barrier method the gradient and the Hessian of the logarithmic barrier function are necessary. SOCCs in the above mentioned form are not continuously differentiable. Therefore SOCCs in Generalized form [2]

$$\|Az + b\|_2^2 \leq (c^T z + d)^2 \quad (3)$$

can be used.

### B. Extended Problem Statement

The algorithm of [1] shall still be used, therefore the general form of the extended problem statement is not changed. Only the constant matrix  $P$  and the vector  $h$ , also constant with respect to the optimization variable  $z$ , are expended with  $p$  rows belonging to the  $p$  new quadratic constraints and  $q$  rows for the conic constraints. Different from the extended vector  $\hat{h}$  the extended matrix  $\hat{P}(z)$  is not constant with respect to  $z$  anymore

$$\hat{P}(z) = \begin{bmatrix} P & & \\ \beta_1^T + z^T \Gamma_1 & & \\ \vdots & & \\ \beta_p^T + z^T \Gamma_p & & \\ -(c_1^T z + 2d_1) c_1^T + (z^T A_1^T + 2b_1^T) A_1 & & \\ \vdots & & \\ -(c_q^T z + 2d_q) c_q^T + (z^T A_q^T + 2b_q^T) A_q & & \end{bmatrix}, \quad (4)$$

$$\hat{h} = \begin{bmatrix} h \\ \alpha_1^T \\ \vdots \\ \alpha_p^T \\ d_1^2 - b_1^T b_1 \\ \vdots \\ d_q^2 - b_q^T b_q \end{bmatrix}. \quad (5)$$

Expanding  $P$  and  $h$  does not change the structure of  $\Phi$  exploited in [1]. So we have not to worry go on with its algorithm. With new  $\hat{h}$  and  $\hat{P}(z)$  the logarithmic barrier function looks like

$$\phi(z) = \sum_{i=1}^{lT+l_f+p+q} -\log(\hat{h}_i - \hat{p}_i^T(z)z) \quad (6)$$

where  $\hat{p}_i^T(z)$  is the  $i$ th rows of  $\hat{P}(z)$  depending on  $z$ . The gradient of the logarithmic barrier function  $\nabla \phi(z)$  necessary

<sup>\*</sup>This work was not supported by any organization  
<sup>1</sup>author hannes.heinemann@st.ovgu.de

to calculate the residual is derived simply by forming  $\hat{P}$  with argument  $2z$  multiplied by  $\hat{d}$ .

$$\nabla\phi(z) = \hat{P}^T(2z)\hat{d} \quad (7)$$

with

$$\hat{d}_i = \frac{1}{\hat{h}_i - \hat{p}_i^T(z)z} \quad (8)$$

To obtain  $\Phi$  in the resulting system of linear equations two additional terms have to be added to the Hessian of  $\phi(z)$ .

$$\begin{aligned} \nabla^2\phi(z) &= \hat{P}(2z)\text{diag}(\hat{d})^2\hat{P}(2z) \\ &+ \sum_{i=lT+lf+1}^{lT+lf+p} \left( \hat{d}_i 2\Gamma_i \right) \\ &+ \sum_{j=lT+lf+p+1}^{lT+lf+p+q} \left( \hat{d}_j - 2(c_j c_j^T - A_j^T A_j) \right) \end{aligned} \quad (9)$$

### C. Selecting $\kappa$

In [1] the use of a fixed  $\kappa$  is proposed. But it is difficult to find one. It should be considered to calculate a new  $\kappa$  once every time step, not every inner step, to have the effect of the barrier function to the cost in same magnitude as the effect of weighting terms like in [4] for linear programs. Adopted for quadratic programs a good  $\kappa$  can be estimated by

$$\kappa = \frac{z^T H z + g^T z}{T(n+m)} \quad (10)$$

### D. Numerical Improvements

## V. RESULTS

### A. Test QPs

Results of Solving Test QPs by [3]

### B. Application Example

## VI. CONCLUSIONS

What are the conclusions?

## ACKNOWLEDGMENT

Acknowledgment.
